Conclusions

Introduction

Umicore in the past - a bit of history ...

Introduction

Umicore today- a materials technology group

“Less is more”

Metal related materials can be efficiently and infinitely recycled, which makes them the basis for sustainable products and services

Introduction

Global market leadership in four divisions

Advanced Materials

#1 World
Top 2 World

Cobalt & Germanium materials
Rechargeable battery materials

Precious Metals Products & Catalysts

Top 3 World
#1 World

Automotive catalysts
Brazing alloys & contact materials

Precious Metals Services

#1 World
#4 World

Precious metals recycling
PGM refiner

Zinc Specialties

#1 World

Zinc specialty products

Introduction

Recycling solutions

Recovering scarce and valuable metals

- The majority of Umicore's raw materials supply for its refining operations comes from secondary materials (end-of life materials and industrial by-products)
- Umicore operates the world's largest precious metals recycling operation in Hoboken (Belgium)
- Hoboken processes some 350,000 tonnes every year from more than 200 different materials

Spent industrial catalysts

Electronic scrap

Spent automotive catalysts

Precious metal bearing raw materials

Non-ferrous byproducts

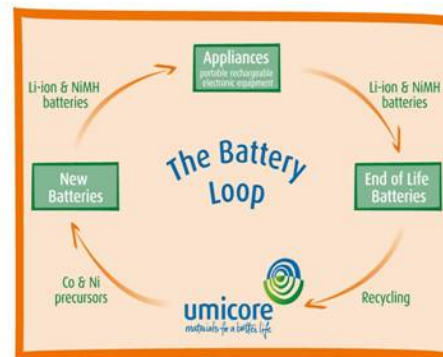

- "Above ground mining" means less energy and less waste → more value

Introduction

Recycling solutions

Recovering scarce metals from e-scrap

- Obsolete mobile phones contain valuable precious metals such as gold (Au), silver (Ag) or palladium (Pd) which Umicore is able to capture
- Currently, only 1-2% of all mobile phones are recycled worldwide, offering huge potential
- Batteries are also recycled

Introduction

Recycling mostly done by melting
 resulting in four main different products that can be further treated

Well structured
 combination of:

Metals and alloys
 Salts
 Oxides
 Organic material
 Et cetera

Homogeneous
 mixture of :

Volatile elements
 Alloys
 Oxides
 Sulphides

Heterogeneous
 separation into:

Fumes
 Oxides
 Sulphides
 Alloys

Introduction

As separation happens on microscopic scale, microanalyses are needed to investigate which element is combined to which other one.

Minimum techniques needed to investigate the repartitioning of elements:

- chemical analyses to determine the sample composition
- X-ray diffraction analyses to identify compounds
- optical microscopy to see the microstructure and to see the compounds
- scanning electron microscopy to see the microstructure and the compounds
- microprobe analyses to determine the composition of the compounds with energy or with wave length dispersive spectrometry

A combination of all these techniques leads generally in the most efficient way to understand which phases are formed, how much and with which elements

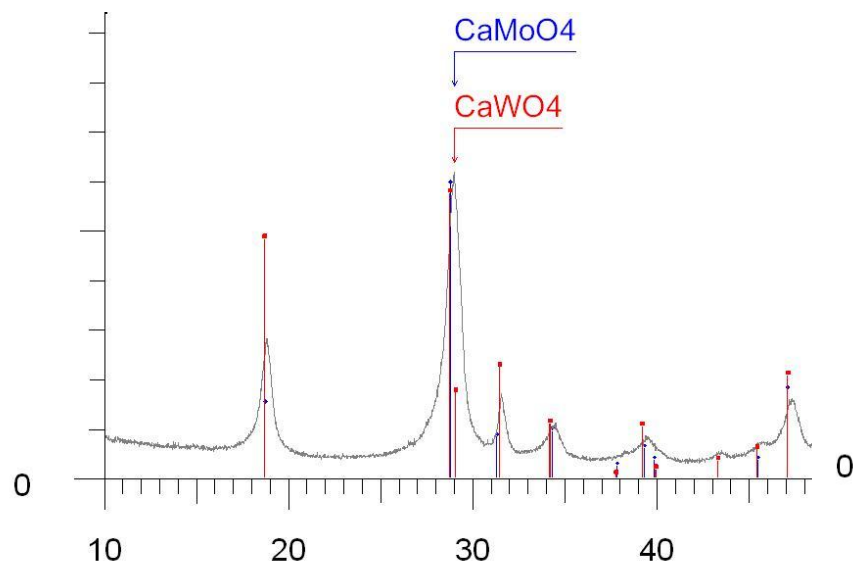

Introduction

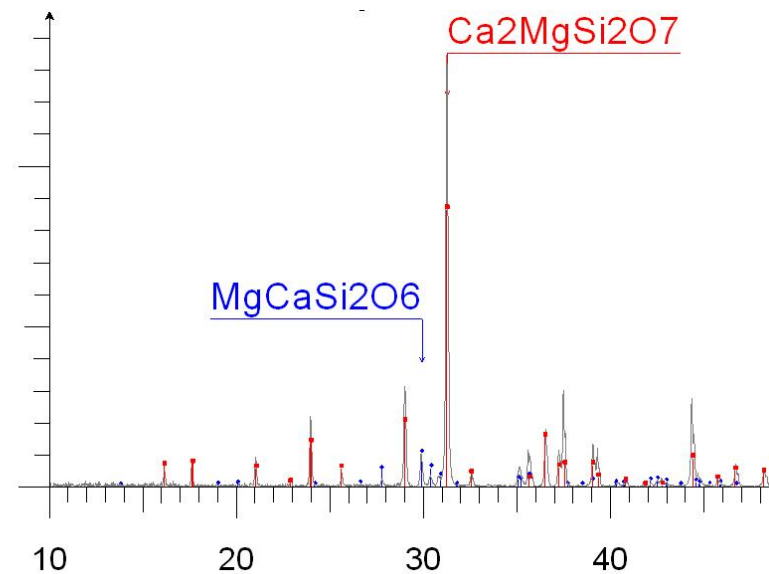

X-ray diffraction analyses

Easiness to identify - Difficulty to determine the real composition

Two or one compound ???

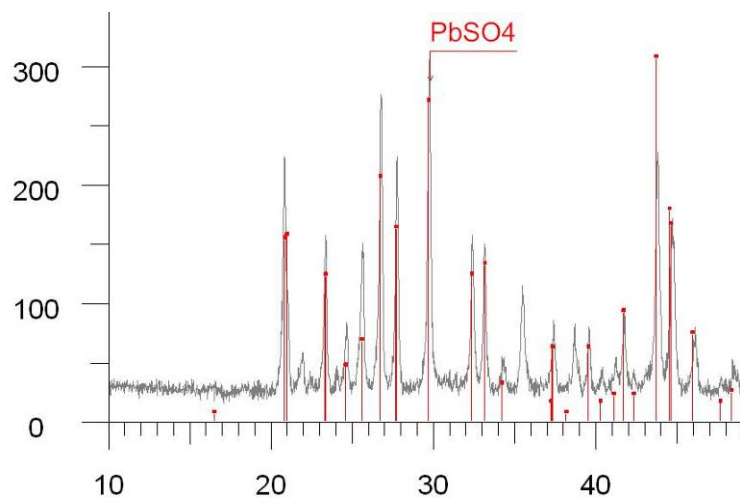

Al ???

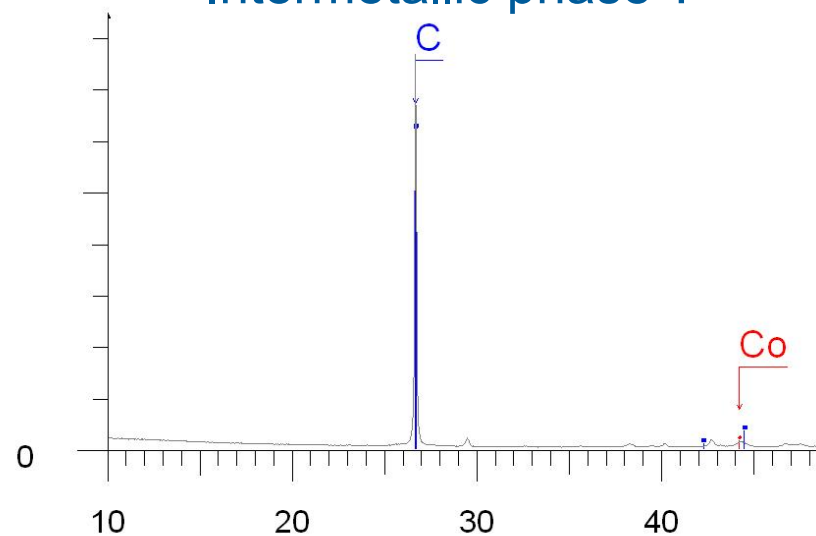

X-ray diffraction analyses

Easiness to identify - Difficulty to solve completely

Other compounds ???

%Co > 70 ???
Intermetallic phase ?

Optical and scanning electron microscopy

LM : Nice colors – SEM : Black & white contrasts

Amount of phases when combining both

Liberation possibility

Microanalyses EDS - WDS

EDS: fast, multi-element, bad Peak/Background, multi Z, spot and area

WDS: slow, element by element, good Peak/Background, focused Z, spot

Composition of a phase

Area analyses by EDS

Composition of the sample ???

48.6% Zn – 51.4% Si

BSE

EDS

Area analyses by EDS

Composition of the sample ???

48.6% Zn – 51.4% Si

BSE

Treated image

71.6 wt% Zn - 28.4 wt% S

7.1 g/cc Zn ↑
2.3 g/cc Si ↑

45.0 vol% Zn - 55.0 vol% Si

Background calculations for WDS

Determining the net intensity – Influence of interfering elements !!

Background calculations for WDS

Mean atomic number MAN: $MAN = \Sigma (wt\%_i \times Z_i) / 100$

SnO₂ 78.8% Sn & 21.2% O

Z=50 for Sn and Z=8 for O

$$MAN \text{ SnO}_2 = (78.8 \times 50 + 21.2 \times 8) / 100 = 41.1$$

Sn 100.0% Sn

Z=50 for Sn

$$MAN \text{ Sn} = (100.0 \times 50) / 100 = 50.0$$

Conclusions

Many products with lots of elements occur in non-ferrous recycling.

X-ray diffraction analyses alone often fail to identify the present compounds.

Microanalyses are essential to characterize the present phases, to know really their composition and their quantity.

Spot analyses have to be realized on many spots to obtain average compositions.

Wave length dispersive spectrometers are indispensable as many elements can not be treated by an energy dispersive spectrometer and as quantification with standards is often necessary.

A background calculating technique based on the mean atomic number enhances drastically the analytical speed of these wave length dispersive analyses.

Conclusions

Area analyses with an energy dispersive spectrometer are not done.

EDS is used for a qualitative check of the present elements in a phase.

Optical micrographs and back scattered electron images contribute moreover to see all present phases, their size and their bonding.

By knowing these analytical data, processes can be further optimized or developed.
